Selection Calculations For Motors

Selecting a motor that satisfies the specifications required by your equipment is an important key to ensuring the desired reliability and economic efficiency of the equipment.
This section introduces the procedure to select the ideal motor, selection calculations, key points of selection and selection examples.

Selection Procedure
An overview of the selection procedure is explained below.

Check the Required Specifications (Equipment specifications)

- Check the required specifications for the motor from the equipment specifications. The general items are explained below.
  - Confirmation of the operation functions
  - Operating time (Operating pattern)
  - Resolution
  - Stopping accuracy
  - Position holding
  - Power supply voltage and frequency
  - Operating environment

Determining the Drive Mechanism

- Determine the drive mechanism. Representative drive mechanisms include simple body of rotation, ball screw, belt pulley, and rack-and-pinion. Along with the type of drive mechanism, determine the dimensions, mass and coefficient, etc. that are required for the load calculation. The general items are explained below.
  - Dimensions and mass (or density) of the load
  - Dimensions and mass (or density) of each part
  - Friction coefficient of the sliding surface of each moving part

Calculate the Load

- Calculate the load torque and inertia at the motor output shaft. Refer to page H-3 for the formula to calculate load torque in representative mechanisms. Refer to page H-4 for the formula to calculate the inertia in representative configurations.

Select Motor Type

- Select the optimal product from standard AC motors, speed control motors, stepper motors or servo motors based on the required specifications.

Selection Calculation

- Determine the most suitable motor after checking that the specifications of the selected motor/gearhead satisfy all of the required specifications, such as mechanical strength, acceleration time and acceleration torque. Since the items that must be checked will vary depending on the motor type, check the selection calculations and selection points on page H-5.

Sizing and Selection Service

We provide sizing and selection services for motor section from your application specification requirements.

Phone
Requests for sizing and section can be made online by contacting our technical support team at:
USA/Canada: TEL: 800-468-3982
Mexico: TEL: 01-800-681-5309

Website
Requests for sizing and section can be made online by contacting our technical support team at techsupport@orientalmotor.com.

Use our online Motor Sizing Tool to calculate the necessary torque, speed, stopping accuracy and the system inertia that is important to consider when selecting a proper motor for the application.
Formula for Load Torque \( T_l \) [N-m] for Each Drive Mechanism

**Formula for Load Torque**

◇ Ball Screw Drive

\[
T_l = \left( F \cdot P_b \cdot \frac{\mu_0 \cdot F_b \cdot P_b}{2\pi} \cdot \frac{1}{i} \right) \text{[N-m]} \quad \cdots \quad (1)
\]

\[
F = F_a + m \cdot g (\sin \theta + \mu \cdot \cos \theta) \text{[N]} \quad \cdots \quad (2)
\]

◇ Pulley Drive

\[
T_l = \frac{\mu \cdot F_a + m \cdot g}{2\pi} \cdot \frac{\pi \cdot D}{i} \quad \text{[N-m]} \quad \cdots \quad (3)
\]

◇ Wire and Belt Drive, Rack-and-Pinion Drive

\[
T_l = \frac{F}{2\pi} \cdot \frac{\pi \cdot D}{i} - \frac{F_a \cdot D^2}{2 \cdot \eta \cdot i} \quad \text{[N-m]} \quad \cdots \quad (4)
\]

\[
F = F_a + m \cdot g (\sin \theta + \mu \cdot \cos \theta) \text{[N]} \quad \cdots \quad (5)
\]

◇ Actual Measurement Method

\[
T_l = \frac{F_a \cdot D}{2} \quad \text{[N-m]} \quad \cdots \quad (6)
\]

\[
F : \text{Force of moving direction [N]}
\]

\[
F_0 : \text{Preload [N] (\approx \frac{1}{3} F)}
\]

\[
\mu_0 : \text{Internal friction coefficient of preload nut (0.1 0.3)}
\]

\[
\eta : \text{Efficiency (0.85 0.95)}
\]

\[
i : \text{Gear ratio (This is the gear ratio of the mechanism -and not the gear ratio of an Oriental Motor's gearhead.)}
\]

\[
F_a : \text{Ball screw lead [m/rev]}
\]

\[
F_b : \text{External force [N]}
\]

\[
F_a : \text{Force when main shaft begins to rotate [N] (\text{Spring balance value [kg]} \times g \text{[m/s}^2\text{]})}
\]

\[
m : \text{Total mass of table and load [kg]}
\]

\[
\mu : \text{Friction coefficient of sliding surface}
\]

\[
\theta : \text{Inclination angle [°]}
\]

\[
D : \text{Final pulley diameter [m]}
\]

\[
g : \text{Gravitational acceleration [m/s}^2\text{]} (9.807)
**Formula for Inertia \( J \) [kg·m\(^2\)]**

- **Inertia of a Cylinder**
  \[
  J_x = \frac{1}{8} m \cdot D_1^4 = \frac{\pi}{32} \rho \cdot L \cdot D_1^4 \quad \text{[kg·m}^2\text{]} \quad \text{⑦}
  \]
  \[
  J_y = \frac{1}{4} m \left( \frac{D_1^4}{4} + \frac{L^2}{2} \right) \quad \text{[kg·m}^2\text{]} \quad \text{⑧}
  \]

- **Inertia of a Hollow Cylinder**
  \[
  J_x = \frac{1}{8} m \cdot (D_1^4 + D_2^4) = \frac{\pi}{32} \rho \cdot L \cdot (D_1^4 - D_2^4) \quad \text{[kg·m}^2\text{]} \quad \text{⑨}
  \]
  \[
  J_y = \frac{1}{4} m \left( \frac{D_1^4 + D_2^4}{4} + \frac{L^2}{2} \right) \quad \text{[kg·m}^2\text{]} \quad \text{⑩}
  \]

- **Inertia on Off-Center Axis**
  \[
  J_x = J_{x0} + m \cdot l^2 = \left( \frac{A^2}{12} + \frac{B^2}{12} \cdot l^2 \right) \quad \text{[kg·m}^2\text{]} \quad \text{⑪}
  \]
  \[
  J_y = \frac{1}{12} \rho \cdot A \cdot B \cdot C \left( A^2 + B^2 \right) \quad \text{[kg·m}^2\text{]} \quad \text{⑫}
  \]

- **Inertia of an Object in Linear Motion**
  \[
  J = m \left( \frac{A}{2} l^2 \right) \quad \text{[kg·m}^2\text{]} \quad \text{⑬}
  \]

  \( A \): Unit Movement [m/rev]

**Conversion formula for the inertia of the motor shaft when using a decelerator**

\[
J_m = \frac{1}{i^2} J_l
\]

**Formula for the relation between \( J \) and \( GD^2 \)**

\[
J = \frac{1}{4} GD^2
\]

**Density**

- Iron: \( \rho = 7.9 \times 10^3 \) [kg/m\(^3\)]
- Stainless steel (SUS304): \( \rho = 8.0 \times 10^3 \) [kg/m\(^3\)]
- Aluminum: \( \rho = 2.8 \times 10^3 \) [kg/m\(^3\)]
- Brass: \( \rho = 8.5 \times 10^3 \) [kg/m\(^3\)]
- Nylon: \( \rho = 1.1 \times 10^3 \) [kg/m\(^3\)]

\( J_x \) : Inertia on \( x \)-axis [kg·m\(^2\)]
\( J_y \) : Inertia on \( y \)-axis [kg·m\(^2\)]
\( J_{x0} \) : Inertia on \( x_0 \)-axis (centered axis) [kg·m\(^2\)]
\( m \) : Mass [kg]
\( D_1 \) : Outer diameter [m]
\( D_2 \) : Inner diameter [m]
\( \rho \) : Density [kg/m\(^3\)]
\( L \) : Length [m]
### Motor Selection Calculations

The following explains the required formulas for controlling a stepper motor or servo motor based on pulse signal.

#### Operating Pattern

For stepper motors, the pattern for acceleration/deceleration operation in the figure on the left is commonly used as operating patterns on pulse speed. The pattern for start/stop operation in the figure on the right can be used when the operating speeds are low and the load inertia is small.

#### Formula for the Number of Operating Pulses \( A \) [Pulse]

The number of operating pulses is expressed as the number of pulse signals that add up to the angle that the motor must rotate to get the load from point A to point B.

\[
A = \frac{l}{\theta_{\text{rev}}} \times \frac{360°}{\theta_s} \]

- \( l \): Traveling Amount from point A to point B [m]
- \( \theta_{\text{rev}} \): Traveling Amount per Motor Rotation [m/rev]
- \( \theta_s \): Step Angle [°]

#### Formula for the Operating Pulse Speed \( f_t \) [Hz]

The operating pulse speed can be obtained from the number of operating pulses, the positioning time and the acceleration (deceleration) time.

1. **For Acceleration/Deceleration Operation**
   
   The level of acceleration (deceleration) time is an important point in the selection. The acceleration (deceleration) time cannot be set easily, because it correlates with the acceleration torque and acceleration/deceleration rate.
   
   Initially, as a reference, calculate the acceleration (deceleration) time at roughly 25% of the positioning time. (The calculation must be adjusted before the final decision can be made.)
   
   \[
t_1 = t_s \times 0.25 \\
   f_t = \frac{A - f_1 \times t_1}{t_s - t_1}
   \]

2. **For Start/Stop Operation**
   
   \[
f_s = \frac{A}{t_s}
   \]

#### Formula for the Acceleration/Deceleration Rate \( T_a \) [ms/kHz]

The acceleration/deceleration rates are the setting values used for the Oriental Motor’s controllers.

The acceleration/deceleration rate indicates the degree of acceleration of pulse speed and is calculated using the formula shown below.

\[
T_a = \frac{t_1}{f_t} \quad \text{Pulse Speed [Hz]} \\
T_s = \frac{f_1}{f_t - f_s} \quad \text{Time [ms]}
\]

- \( f_t \): Starting Pulse Speed [Hz]
- \( f_s \): Operating Pulse Speed [Hz]
- \( A \): Number of Operating Pulses
- \( t_1 \): Positioning Time [s]
- \( f_1 \): Acceleration (Deceleration) Time [s]

- Calculate the pulse speed in full step conversion.
- For this formula, the unit for speed is [Hz] and the unit for time is [ms].

#### Conversion Formula for the Operating Speed \( N_u \) [r/min]

from the Operating Pulse Speed \( f_t \) [Hz]

\[
N_u = f_t \times \frac{\theta_s}{360°} \times 60
\]

#### Formula for the Required Torque \( T_r \) [N·m]

The required torque is calculated by multiplying the sum of load torque and acceleration torque by the safety factor.

\[
T_r = (T_L + T_a) S_f
\]

- \( T_r \): Required Torque [N·m]
- \( T_L \): Load Torque [N·m]
- \( T_a \): Acceleration Torque [N·m]
- \( S_f \): Safety Factor

#### Formula for the Effective Load Torque \( T_{L\text{eff}} \) [N·m]

Calculate the effective load torque when selecting the servo motors and BXII Series brushless motors.

When the required torque for the motor varies over time, determine if the motor can be used by calculating the effective load torque.

The effective load torque becomes particularly important for operating patterns such as fast-cycle operations where acceleration/ deceleration is frequent.

\[
T_{L\text{eff}} = \sqrt{\frac{(T_a + T_d) \cdot t_1 + T_r \cdot t_2 + (T_a - T_d) \cdot t_3}{t_4}}
\]

- \( T_d \): Torque Pattern [N·m]
- \( T_r \): Load Torque Pattern [N·m]
- \( T_a \): Acceleration Pattern [N·m]
- \( t_1 \): Time [s]
- \( t_2 \): Time [s]
- \( t_3 \): Time [s]
- \( t_4 \): Time [s]
Selection Points

Since there are differences in characteristics between standard AC motors, brushless motors, stepper motors and servo motors, there will also be differences in points (check items) when selecting a motor.

Standard AC Motors

① Speed Variation by Load

The actual speed of standard AC motors is 2~20% lower than its synchronous speed under the influence of the load torque. When selecting a standard AC motor, the selection should take this decrease in speed into account.

② Time Rating

There are differences in continuous rating and short time rating depending on the motor type, even for motors with the same output power. Motor selection should be based on the operating time (pattern).

③ Permissible Load Inertia of the Gearhead

If instantaneous stop (with brake pack, etc.), frequent intermittent operations or instantaneous bi-directional operation will be performed using a motor with a gearhead, an excessive load inertia may damage the gearhead. Selections must be made for these values, so that the load inertia does not exceed the permissible load inertia of the gearhead. (Refer to Page C-16)

Brushless Motors

① Permissible Torque

Brushless motor combination types with a dedicated gearhead installed are listed on the permissible torque table based on the output gear shaft. Select products in which the load torque does not exceed the permissible load torque.

② Permissible Inertia

A permissible inertia is specified for the brushless motor for avoiding alarms using regenerative power during deceleration and for stable speed control. Select products in which the inertia does not exceed the permissible value. For the combination type, there is a permissible inertia combination type. Select products with values that do not exceed the values of the combination types.

③ Effective Load Torque

When operating the BXII Series with frequent starts and stops, make sure the effective load torque does not exceed the rated torque. If the rated torque is exceeded, the overload protective function activates and stops the motor.

Stepper Motors

① Check the Required Torque

For stepper motors, select motors whose duty region (operating speed \(N_{VH}\)) and the required torque \(T_{IR}\) falls within the pullout torque curve.

Safety Factor: \(S_f\) (Reference Value)

<table>
<thead>
<tr>
<th>Product</th>
<th>Safety Factor (Reference Value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stepper Motors</td>
<td>1.5~2</td>
</tr>
</tbody>
</table>

② Considering Temperature Rise

The stepper motor will have an increase in temperature if operated continuously over a long period of time. Exceeding the temperature of heat-resistant class 130 (B) inside the motor may deteriorate its insulation performance. Temperature rise will vary based on the operating speed, load conditions and installation conditions. The stepper motor should be used at an operating duty of 50% or less. If the operating duty exceeds 50%, choose a motor with a sufficient margin of torque or use methods to lower the running current.

\[
\text{Operating Duty} = \frac{\text{Running time}}{\text{Running + Stopping Time}} \times 100
\]

③ Check the Acceleration/Deceleration Rate

If the duty region (operating speed \(N_{VH}\) and the required torque \(T_{IR}\)) of the stepper motor falls within the pullout torque curve, the specified equipment can be operated. Controllers, when set for acceleration/ deceleration, adjust the pulse speed in steps using output pulse signals. Sudden acceleration/deceleration causes the pulse speed step to become large. Therefore, if large inertias are present in this condition, there is a possibility that the motor cannot be driven even when sudden acceleration/deceleration direction is given. Check that the reference values are equal to or higher than the acceleration/ deceleration rates shown in the table so that the selected motor can be operated more reliably.

Acceleration/Deceleration Rate

(Combination reference values with EMP Series)

<table>
<thead>
<tr>
<th>Product</th>
<th>Frame Size</th>
<th>Acceleration/Deceleration Rate (T_S) [ms/kHz]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\alpha_{\text{STEP}})</td>
<td>28 (30), 42, 60, 85 (90)</td>
<td>0.5 or more (*)</td>
</tr>
<tr>
<td>0.36°/0.72°</td>
<td>20, 28, 42, 60</td>
<td>20 or more</td>
</tr>
<tr>
<td>Stepper Motors</td>
<td>85 (90)</td>
<td>30 or more</td>
</tr>
<tr>
<td>0.9°/1.8°</td>
<td>20, 28 (30), 42, 50, 56.4, 60</td>
<td>50 or more</td>
</tr>
<tr>
<td>Stepper Motors</td>
<td>85 (90)</td>
<td>75 or more</td>
</tr>
</tbody>
</table>

\(*) When using \(\alpha_{\text{STEP}}\), this item does not need to be checked. The values in the table represent the lower limit of settings for the EMP Series.

④ Check the Inertia Ratio

Calculate the inertia ratio using the following formula:

\[
\text{Inertia Ratio} = \frac{J_{S}}{J_{C}}
\]

For Geared Motors

\[
\text{Inertia Ratio} = \frac{J_{S}}{J_{C} \cdot i^2}
\]

Large inertia ratios in stepper motors cause large overshooting and undershooting during starting and stopping, which can affect rise times and settling times. Controllers, when set for acceleration/ deceleration, adjust the pulse speed in steps using output pulse signals. Sudden acceleration/deceleration causes the pulse speed step to become large. Therefore, if the inertia ratio is large, operation may not be possible. Check that the reference values are less than or equal to inertia ratios shown in the table so that the selected motor can be operated more reliably.

Inertia Ratio (Reference values)

<table>
<thead>
<tr>
<th>Product</th>
<th>Frame Size</th>
<th>Inertia Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\alpha_{\text{STEP}})</td>
<td>28, 42, 60, 85</td>
<td>30 or less</td>
</tr>
<tr>
<td>Stepper Motors</td>
<td>20, 28, 35</td>
<td>5 or less</td>
</tr>
<tr>
<td>42, 50, 56.4, 60, 85</td>
<td>10 or less</td>
<td></td>
</tr>
</tbody>
</table>

When the values in the table are exceeded, we recommend a geared type motor.
Servo Motors

1. Permissible Inertia
   A permissible inertia is specified for the servo motor for stable control. The inertia of the servo motor must be lower than the permissible value.

<table>
<thead>
<tr>
<th>Product</th>
<th>Permissible Load Inertia</th>
</tr>
</thead>
</table>
| NX Series | 50 times the rotor inertia or less

*Automatic tuning allows operation up to 50 times the rotor inertia, manual tuning allows operation up to 100 times the rotor inertia.

2. Rated Torque
   The motor can be driven when the ratio of load torque $T_L$ and rated torque of the servo motor is $1.5 - 2$ or more.

   $\frac{T_L}{T_{ rated}} \geq 1.5 - 2$

3. Maximum Instantaneous Torque
   Check that the required torque is less than the maximum instantaneous torque of the servo motor. (Ensure that the safety factor of required torque $S_f$ is at 1.5 - 2 or more.)

   Note that the time that max. instantaneous torque can be used for varies depending on the motor.

Max. Instantaneous Torque and Operating Time

<table>
<thead>
<tr>
<th>Product</th>
<th>Operating Time</th>
<th>Maximum Instantaneous Torque</th>
</tr>
</thead>
<tbody>
<tr>
<td>NX Series</td>
<td>Within approx. 0.5 seconds</td>
<td>At 3 times the rated torque (at rated speed)</td>
</tr>
</tbody>
</table>

4. Effective Load Torque
   The motor can be driven when the effective load safety factor, which is the ratio of an effective load torque and a rated torque of servo motor, is $1.5 - 2$ or more.

   Effective Load Safety Factor $= \frac{Rated Torque}{Effective Load Torque}$

5. Settling Time
   There is a time lag between a position command sent by pulse signal and the servo motor’s actual operation. This difference is called the settling time.

   Therefore, the real positioning time is the sum of the positioning time calculated from the operating pattern and the settling time.

Selection Examples

Ball Screw Mechanism

**Using Standard AC Motors**

1. Specifications and Operating Conditions of the Drive Mechanism
   This selection example demonstrates an electromagnetic brake motor for use on a table moving vertically on a ball screw.

   In this case, a motor must be selected that meets the following required specifications.

   - Total mass of the table and load $m = 45$ [kg]
   - Table speed $V = 15 \pm 2$ [mm/s]
   - External force $F_A = 0$ [N]
   - Ball screw tilt angle $\theta = 90$ [°]
   - Total length of ball screw $L_s = 800$ [mm]
   - Ball screw shaft diameter $D_s = 20$ [mm]
   - Ball screw lead $P_h = 5$ [mm]
   - Distance moved for one rotation of ball screw $A = 5$ [mm]
   - Ball screw efficiency $\eta = 0.9$
   - Ball screw material Iron (Density $\rho = 7.9 \times 10^3$ [kg/m$^3$])
   - Internal friction coefficient of preload nut $\mu = 0.3$
   - Friction coefficient of sliding surface $\mu = 0.05$
   - Motor power supply Three-Phase 230 VAC 60 Hz
   - Operating time Intermittent operation, 5 hours/day
   - Load with repeated starts and stops
   - Required load holding

2. Determine the Gear Ratio
   Speed at the gearhead output shaft $N_c = \frac{V \cdot 60}{A} = \frac{(15 \pm 2) \times 60}{5} = 180 \pm 24$ [r/min]

   Because the rated speed for a 4-pole motor at 60 Hz is 1550 [r/min], the gear ratio is calculated as follows:

   $\frac{1450\sim1550}{1500\sim1800} = \frac{1450\sim1550}{180 \pm 24} = 7.1\sim9.9$

   This gives us a gear ratio of $i = 9$.

3. Calculate the Required Torque $T_{ ru }$ [N-m]
   Force of moving direction $F = F_s + m \cdot g (\sin \theta + \mu \cdot \cos \theta)$
   $= 0 + 45 \times 9.807 (\sin 90^\circ + 0.05 \cos 90^\circ)$
   $= 441$ [N]

   Ball screw preload $F_s = \frac{F}{i} = 147$ [N]

   Load torque $T_L = \frac{F \cdot P_h}{2 \pi \cdot \eta} + \frac{\mu \cdot F_s \cdot P_h}{2 \pi}$
   $= \frac{441 \times 5 \times 10^{-3}}{2 \pi \times 0.9} + \frac{0.3 \times 147 \times 5 \times 10^{-3}}{2 \pi}$
   $= 0.426$ [N-m]

   Consider the safety factor $S_f = 2$.

   $T_L = T_{ ru } \cdot S_f = 0.426 \times 2 = 0.86$ [N-m]
Select an electromagnetic brake motor and gearhead satisfying the permissible torque of gearhead based on the calculation results (gear ratio \( i = 9 \), load torque \( T_{L} = 0.86 \text{ [N·m]} \)) obtained so far. Here, 4IK25GN-SW2M and 4GN95A are tentatively selected as the motor and gearhead respectively, by referring to the "Gearmotor = Torque Table" on page C-73.

Next, convert this load torque to a value on the motor output shaft to obtain the required torque \( T_{N} \), as follows:

\[
T_{N} = \frac{T_{L}}{i \cdot \eta_{G}} = \frac{0.86}{9 \times 0.81} = 0.118 \text{ [N·m]} = 118 \text{ [mN·m]}
\]

(Gearhead efficiency \( \eta_{G} = 0.81 \))

The starting torque of the 4IK25GN-SW2M motor selected earlier is 160 [mN·m]. Since this is greater than the required torque of 118 [mN·m], this motor can start the mechanism in question.

Next, check if the gravitational load acting upon the mechanism in standstill state can be held with the electromagnetic brake.

Here, the load equivalent to the load torque obtained earlier is \( T'_{M} \), which is assumed to act. Here, the load equivalent to the load torque obtained earlier is \( T'_{M} \), which is assumed to act. The static friction torque generated by the electromagnetic brake of the 4IK25GN-SW2M motor selected earlier is \( 0.81 \times 9 \times 60 \text{ [mN·m]} \). Since this is greater than the required torque of \( 0.86 \times 9 \times 0.81 \text{ [N·m]} \), this motor can start the mechanism in question.

The static friction torque generated by the electromagnetic brake of the 4IK25GN-SW2M motor selected earlier is \( 0.86 \times 9 \times 0.81 \text{ [N·m]} \), which is greater than 95.6 [mN·m] required for the load holding.

(4) Check the Moment of Inertia \( J \) [kg·m²]

\[
J = \frac{\pi}{32} \cdot \rho \cdot Ls \cdot Ds^4
\]

\[
= \frac{\pi}{32} \times 7.9 \times 10^3 \times 800 \times 10^{-1} \times (20 \times 10^{-3})^4
\]

\[
= 0.993 \times 10^{-4} \text{ [kg·m²]} \]

Inertia of table and load \( J_{o} \) is calculated as follows:

\[
J_{o} = m \left( \frac{\Delta}{2} \right)^2
\]

\[
= 45 \times \left( \frac{5 \times 10^{-3}}{2} \right)^2
\]

\[
= 0.286 \times 10^{-4} \text{ [kg·m²]} \]

Inertia at the gearhead shaft \( J \) is calculated as follows:

\[
J = J_{o} + J_{s} = 0.993 \times 10^{-4} + 0.286 \times 10^{-4}
\]

\[
= 1.28 \times 10^{-4} \text{ [kg·m²]} \]

Therefore, \( J < J_{o} \), the inertia is less than the permissible value, so there is no problem. There is margin for the torque, so the traveling speed is checked with the speed under no load (approximately 1750 r/min).

\[
V = \frac{N_{M} \cdot \rho_{A}}{60 \cdot i} = \frac{1750 \times 5 \times 60}{9 \times 0.81} = 16.2 \text{ [mm/s]} \]

\( N_{M} \) Motor speed

This confirms that the motor meets the specifications. Based on the above, 4IK25GN-SW2M and 4GN95A are selected as the motor and gearhead, respectively.
(4) Calculate the Required Torque \( T_M [\text{N-m}] \) (Refer to page H-5)

1. Calculate the load torque \( T_L [\text{N-m}] \)
   
   Force of Moving Direction \( F = F_s + m \cdot g \cdot (\sin \theta + \mu \cdot \cos \theta) \)
   
   \[ F = 0 + 40 \times 9.807 (\sin 0' + 0.05 \cos 0') = 19.6 [\text{N}] \]
   
   Preload \( F_s = \frac{F}{3} = \frac{19.6}{3} = 6.53 [\text{N}] \)

   Load Torque \( T_L = F \cdot \frac{J_L}{2\pi \cdot r} + \mu \cdot F_s \cdot \frac{J_L}{2\pi \cdot r} \)
   
   \[ T_L = 19.6 \times 15 \times 10^{-3} + 0.3 \times 6.53 \times 15 \times 10^{-3} \]
   
   \[ T_L = 0.0567 [\text{N\cdotm}] \]

2. Calculate the acceleration torque \( T_a [\text{N-m}] \)

   1-1 Calculate the inertia \( J_o [\text{kg\cdotm}^2] \)
   
   (Refer to the formula on page H-4)
   
   Inertia of Ball Screw
   
   \[ J_o = \frac{\pi}{32} \cdot \rho \cdot \varphi \cdot \Delta \varphi \]
   
   \[ J_o = \frac{\pi}{32} \times 7.9 \times 10^2 \times 600 \times 10^{-3} \times (15 \times 10^{-3})^2 \]
   
   \[ J_o = 0.236 \times 10^{-4} [\text{kg\cdotm}^2] \]

   Inertia of Table and Load \( J_t = \frac{m}{2\pi \cdot r} \)
   
   \[ J_t = 40 \times (\frac{15 \times 10^{-3}}{2\pi}) \]
   
   \[ J_t = 2.28 \times 10^{-4} [\text{kg\cdotm}^2] \]

   Inertia \( J_o = J_o + J_t \)
   
   \[ J_o = 0.236 \times 10^{-4} + 2.28 \times 10^{-4} = 2.52 \times 10^{-4} [\text{kg\cdotm}^2] \]

1-2 Calculate the acceleration torque \( T_a [\text{N-m}] \)

   \[ T_a = \frac{J_o + J_t}{9.55} \cdot \frac{N_u}{n} \]
   
   \[ T_a = \frac{2.52 \times 10^{-4}}{9.55} \cdot \frac{1200}{0.2} \]
   
   \[ T_a = 628 J_o + 0.158 [\text{N\cdotm}] \]

The formula for calculating acceleration torque with pulse speed is shown below. Calculation results are the same.

\[ T_a = \frac{J_o + J_t}{180} \cdot \frac{\dot{\theta} - \theta_i}{n} \]

\[ T_a = 2.52 \times 10^{-4} \times \frac{0.72}{180} \times \frac{10000}{0.2} \]

\[ T_a = 628 J_o + 0.158 [\text{N\cdotm}] \]

3. Calculate the required torque \( T_M [\text{N-m}] \)

   Safety factor \( S_f = 2 \).

   \[ T_M = \frac{(T_l + T_a) S_f}{S_f} \]
   
   \[ T_M = (0.0567 + (628 J_o + 0.158)) \times 2 \]
   
   \[ T_M = 1256 J_o + 0.429 [\text{N\cdotm}] \]
Using Servo Motors

(1) Specifications and Operating Conditions of the Drive Mechanism

The following is an example of how to select a servo motor to drive a single axis table:

- Max. table speed: \( V_L = 0.2 \text{ [m/s]} \)
- Resolution: \( M = 0.02 \text{ [mm]} \)
- Motor power supply: Single-Phase 115 VAC
- Total mass of table and load: \( m = 100 \text{ [kg]} \)
- External force: \( F_A = 29.4 \text{ [N]} \)
- Friction coefficient of sliding surface: \( \mu = 0.04 \)
- Ball screw efficiency: \( \eta = 0.9 \)
- Internal friction coefficient of preload nut: \( \mu_o = 0.3 \)
- Shaft diameter of ball screw: \( D_s = 25 \text{ [mm]} \)
- Overall length of ball screw: \( L_s = 1000 \text{ [mm]} \)
- Ball screw lead: \( P_s = 10 \text{ [mm]} \)
- Ball screw material: Iron (Density \( \rho = 7.9 \times 10^3 \text{ [kg/m}^3]\))
- Operating cycle: Operation for 2.1 seconds/stopped for 0.4 seconds (repeated)

(2) Calculate the Required Resolution \( \theta \)

Calculate the motor resolution from the resolution required for the table drive.

\[
\theta = \frac{360 \times M}{P_s} = \frac{360 \times 0.02}{10} = 0.72^\circ
\]

The resolution of the NX Series, \( \theta_M = 0.367^\circ \) (pulse (factory setting)) satisfies this requirement.

(3) Determine an Operating Pattern

Calculate the motor speed \( N_w \) from the formula below.

\[
N_w = \frac{60 \times V_L}{P_s} = \frac{60 \times 0.2}{10 \times 10^{-3}} = 1200 \text{ [r/min]}
\]

Determine the speed pattern using \( N_w \), the operating cycle and the acceleration/deceleration time.

(4) Calculate the Load Torque \( T_L \) [N·m]

Operation direction load \( F = F_A + m \cdot g (\sin \theta + \mu \cdot \cos \theta) \)
- \( = 29.4 + 100 \times 9.807 (\sin 0.72 + 0.04 \cos 0.72) \)
- \( = 68.6 \text{ [N]} \)

Load Torque of the Motor Shaft Conversion

\[
T_L = \frac{F_s \cdot P_s}{2\pi \cdot \eta} + \frac{\mu_o \cdot F_s \cdot P_s}{2\pi}
\]

\[
= \frac{68.6 \times 10 \times 10^{-3}}{2\pi \times 0.9} + \frac{0.3 \times 22.9 \times 10 \times 10^{-3}}{2\pi}
\]

\( \approx 0.13 \text{ [N·m]} \)

Here \( F_s = \frac{1}{3} F \) represents the ball screw preload.

(5) Calculate the Inertia \( J_L \) [kg·m²]

Inertia of Ball Screw

\[
J_s = \frac{\pi}{32} \cdot \rho \cdot L_s \cdot D_s^4
\]

\( = \frac{\pi}{32} \times 7.9 \times 10^3 \times 1000 \times 10^{-3} \times (25 \times 10^{-3})^4 \)

\( = 3.03 \times 10^{-8} \text{ [kg·m²]} \)

Inertia of Table and Load \( J_L = m \cdot \frac{P_s^2}{2\pi} \)

\( = 100 \times \left( \frac{10 \times 10^{-3}}{2\pi} \right) \)

\( = 2.53 \times 10^{-6} \text{ [kg·m²]} \)

(6) Tentative Servo Motor Selection

Safety factor \( SF = 1.5 \).

Load torque \( F_L = SF \cdot T_L \)

\( = 1.5 \times 0.13 = 0.195 \text{ [N·m]} \)

Inertia \( J_L = 5.56 \times 10^{-6} \text{ [kg·m²]} \)

Therefore, select the servo motor which has a speed of 1200 [r/min], outputs the rated torque 0.195 [N·m] or more and whose permissible inertia is 5.56 × 10⁻⁶ [kg·m²] or more.

\( \rightarrow \text{NX620AA-3} \)

- Rated speed \( N = 3000 \text{ [r/min]} \)
- Rated torque \( T_M = 0.637 \text{ [N·m]} \)
- Rotor inertia \( J_M = 0.162 \times 10^{-4} \text{ [kg·m²]} \)
- Permissible inertia \( J = 8.1 \times 10^{-4} \text{ [kg·m²]} \)
- Max. instantaneous torque \( T_{MAX} = 1.91 \text{ [N·m]} \)

is ideal.

(7) Calculate the Acceleration Torque \( T_a \) [N·m] and Deceleration Torque \( T_d \) [N·m]

Calculate the acceleration/deceleration torque using the formula below.

\[
T_a (= T_d) = \frac{(J_u + J_L) \cdot N_w}{\eta} = \frac{(5.56 \times 10^{-6} + 0.162 \times 10^{-4}) \times 1200}{9.55 \times 0.1} \approx 0.72 \text{ [N·m]}
\]

(8) Calculate the Required Torque \( T \) [N·m]

\[
T = T_a + T_i = 0.72 + 0.13 = 0.85 \text{ [N·m]}
\]

The required torque is less than the max. instantaneous torque of NX620AA-3 of 1.91 [N·m], so the NX620AA-3 can be used.

(9) Determine a Torque Pattern

Determine a torque pattern using operating cycle, acceleration/deceleration torque, load torque and acceleration time.

\[
\begin{align*}
&\text{Speed [r/min]} \\
&\begin{array}{c|c|c|c}
\text{Time [s]} & n = n = 0.1 & 2.1 & 0.4 \\
& 1.9 & n = 0.1 & \\
& 2.5 & & &
\end{array}
\end{align*}
\]
Calculate the effective load torque \( T_{\text{rms}} \) [N·m]

\[
T_{\text{rms}} = \sqrt{\left(T_a + T_f\right)^{t_1} + T_f \cdot t_2 + \left(T_a - T_f\right)^{t_1} \cdot t_2}
\]

where

\[
\begin{aligned}
T_a &= (0.72 + 0.13)^{t_1} \times 0.1 + 0.13^2 \times 1.9 + (0.72 - 0.13)^{t_1} \times 0.1, \\
T_f &= 1.5^t_2 \\
T_{\text{rms}} &= 2.5
\end{aligned}
\]

Here, \( t_1 = 0.1 \) [s] from the operating cycle and \( t_2 = 0.1 \) [s] for acceleration and deceleration time. Therefore, \( t = 2.1 = 0.1 \times 2 = 1.9 \) [s]

The ratio (effective load safety factor) of \( T_{\text{rms}} \) and the rating torque of servo motor \( T_m \) is expressed by the formula below.

\[
\frac{T_{\text{rms}}}{T_m} = 0.637 \times 0.24 = 2.65
\]

Generally a motor can operate at an effective load safety factor of 1.5–2 or more.
(4) Check the Inertia $J$ [kg·m²]

Inertia of Belt and Load $J_0 = m_D \left( \frac{x \cdot D}{2\pi} \right)^2$

$= 25 \times \left( \frac{90 \times 10^{-3}}{2\pi} \right)^2$

$= 0.113 \times 10^{-4}$ [kg·m²]

Inertia of Roller $J_0 = \frac{1}{8} \cdot m_0 \cdot D^2$

$= \frac{1}{8} \times 1 \times (90 \times 10^{-3})^2$

$= 0.102 \times 10^{-4}$ [kg·m²]

Calculate the load inertia for the gearhead output shaft $J$.

Take into account that there are 2 rollers ($J_{ol}$).

$J = J_0 + 2J_{ol}$

$= 0.113 \times 10^{-4} + 10.2 \times 10^{-4} \times 2$

$= 0.288 \times 10^{-4}$ [kg·m²]

The value of the permissible inertia $J_{o}$ for the 5IK40UA-50A can be found on the specifications table on page C-18.

$J_{o} = 275 \times 10^{-4}$ [kg·m²] (During instantaneous stop)

Therefore, since $J < J_{o}$, the inertia is less than the permissible value, so there is no problem. Since the motor selected has a rated torque of 11.2 [N·m], which is larger than the actual load torque, the motor will operate at a higher speed than the rated speed.

Therefore, use the speed that is without load (approx. 1750 r/min) to calculate belt speed, and check whether the selected product meets the required specifications.

$V = \frac{N}{60} \times \pi \times D = 1750 \times \pi \times 60 \times 60 / 60 = 165$ [mm/s]

which is larger than the actual load torque, the motor will operate at a higher speed than the rated speed.

This confirms that the motor meets the specifications.

Therefore, the 5IK40UA-50A motor is selected.

### Using Low-Speed Synchronous Motors (SMK Series)

(1) Specifications and Operating Conditions of the Drive Mechanism

The mass of load is selected that can be driven with SMK5100A-AA when the belt-drive table shown in Fig. 1 is driven in the operation pattern shown in Fig. 2.

![Fig. 1 Example of Belt Drive](image)

![Fig. 2 Operating Pattern](image)

Low-speed synchronous motors share the same basic operating principle with 1.8° stepper motors. Accordingly, the torque for a low-speed synchronous motor is calculated in the same manner as for a 1.8° stepper motor.

(2) Belt Speed $V$ [mm/s]

Check the belt (load) speed

$V = \frac{\pi \cdot D \cdot N}{60} = \frac{\pi \times 30 \times 72}{60} = 113$ [mm/s]

(3) Calculate the Required Torque $T_r$ [N·m]

Frictional coefficient of sliding surfaces $\mu = 0.04$

Belt and pulley efficiency $\eta = 0.9$

Load Torque $T_r = \frac{F \cdot D}{2 \cdot \eta} = \frac{0.589 \times 30 \times 10^{-3}}{2 \times 0.9} = 9.82 \times 10^{-3}$ [N·m]

(4) Calculate the Moment of Inertia $J_l$ [kg·m²]

Inertia of belt and load $J_0 = m_D \left( \frac{x \cdot D}{2\pi} \right)^2$

$= 1.5 \times \left( \frac{90 \times 10^{-3}}{2\pi} \right)^2$

$= 3.38 \times 10^{-4}$ [kg·m²]

Inertia of Roller $J_{rol} = \frac{1}{8} \cdot m_0 \cdot D^2$

$= \frac{1}{8} \times 0.1 \times (90 \times 10^{-3})^2$

$= 0.113 \times 10^{-4}$ [kg·m²]

The inertia $J_l$ is calculated as follows:

Take into account that there are two rollers ($J_{ol}$).

$J_l = J_0 + 2J_{rol} = 3.38 \times 10^{-4} + 0.113 \times 10^{-4} \times 2 = 3.5 \times 10^{-4}$ [kg·m²]
(5) Calculate the Acceleration Torque \( T_a \) [N⋅m]  
Calculate the start acceleration torque.  
\[
T_a = (J_i + J_e) \cdot \left( \frac{\pi \cdot \theta s}{180 \cdot n} \right) \cdot f^2 = (J_i + 3.5 \times 10^{-4}) \times \frac{\pi \times 7.2}{180 \times 0.5} \times 60^2 \\
= 905 J_i + 0.32 \text{ [N⋅m]}
\]
Here, \( \theta s = 7.2^\circ \), \( f = 60 \text{ Hz} \), \( n = 3.6^\circ/\theta s = 0.5 \)  
\( J_i \): Rotor Inertia  

(6) Calculate the Required Torque \( T_u \) [N⋅m] (Safety factor \( S_f = 2 \))  
Required Torque \( T_u = (T_i + T_a) S_f \)  
\[
= (0.82 \times 10^{-3} + 905 J_i + 0.32) \times 2 \\
= 1810 J_i + 0.66 \text{ [N⋅m]}
\]

(7) Select a Motor  
Select a motor that satisfies both the required torque and the permissible inertia.  

<table>
<thead>
<tr>
<th>Motor</th>
<th>Rotor Inertia [kg⋅m²]</th>
<th>Permissible Inertia [kg⋅m²]</th>
<th>Output Torque [N⋅m]</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMK5100A-AA</td>
<td>1.4×10^{-4}</td>
<td>7×10^{-4}</td>
<td>1.12</td>
</tr>
</tbody>
</table>

When the required torque is calculated by substituting the rotor inertia, \( T_u \) is obtained as 0.914 [N⋅m], which is below the output torque. Next, check the permissible inertia. Since the inertia calculated in (4) is also below the permissible inertia, **SMK5100A-AA** can be used in this application.

### Using Brushless Motors

(1) Specifications and Operating Conditions of the Drive Mechanism  
Here is an example of how to select a brushless motor to drive a belt conveyor.

![belt conveyor diagram](image)

Here, \( F = 0.05 \text{ m/s}^2 \)  
Motor power supply: Single-Phase 115 VAC  
Belt conveyor drive  
Roller diameter \( D \) = 0.1 [m]  
Roller mass \( m_2 \) = 1 [kg]  
Total mass of belt and load \( m_1 \) = 7 [kg]  
External force \( F_A \) = 0 [N]  
Friction coefficient of sliding surface \( \mu \) = 0.3  
Belt and roller efficiency \( \eta \) = 0.9

(2) Find the Required Speed Range  
For the gear ratio, select 15:1 (speed range: 5.3 ∼ 200) from the “Gearmotor – Torque Table of Combination Type” on page D-28 so that the minimum/maximum speed falls within the speed range.  
\[
N_c = \frac{60 \times V_s}{\pi \cdot D} \quad N_c: \text{Speed at the gearhead shaft}
\]

Belt speed \( 0.015 \text{ m/s} \)  
\[
\frac{60 \times 0.05}{\pi \times 0.1} = 9.55 \text{ [r/min]} \quad \text{(Minimum speed)}
\]

Belt speed \( 1 \text{ m/s} \)  
\[
\frac{60 \times 1}{\pi \times 0.1} = 191 \text{ [r/min]} \quad \text{(Maximum speed)}
\]

(3) Calculate the Moment of Inertia \( J_m \) [kg⋅m²]  
Inertia of belt and load \( J_{m1} = m_1 \left( \frac{\pi \cdot D^2}{2 \pi} \right) = 7 \times \left( \frac{\pi \times 0.1}{2 \pi} \right)^2 = 175 \times 10^{-4} \text{ [kg⋅m²]} \)

Inertia of roller \( J_{m2} = \frac{1}{8} \times m_2 \cdot D^2 = 12.5 \times 10^{-4} \text{ [kg⋅m²]} \)

The inertia \( J_c \) is calculated as follows:  
Take into account that there are two rollers \( (J_{m2}) \).  
\[
J_c = J_{m1} + 2 J_{m2} = 175 \times 10^{-4} + 12.5 \times 10^{-4} \times 2 = 200 \times 10^{-4} \text{ [kg⋅m²]}
\]

From the specifications on page D-29, the permissible load inertia of **BMU5120A-15A-3** is 225 × 10⁻⁴ [kg⋅m²].

(4) Calculate the Load Torque \( T_l \) [N⋅m]  
Friction coefficient of sliding surface \( F = F_A + m_1 \cdot g \cdot (\sin \theta + \mu \cdot \cos \theta) = 0 + 7 \times 9.807 \cdot (\sin 0^\circ + 0.3 \cdot \cos 0^\circ) = 20.6 \text{ [N]} \)

Load torque \( T_l = \frac{F \cdot D}{2 \cdot g} = \frac{20.6 \times 0.1}{2 \times 0.9} = 1.15 \text{ [N⋅m]} \)

Select **BMU5120A-15A-3** from the “Gearmotor – Torque Table of Combination Type” on page D-28.  
Since the permissible torque is 5.2 [N⋅m], the safety factor is \( T_u / T_l = 5.2 / 1.15 \approx 4.5 \).  
Usually, a motor can operate at the safety factor of 1.5 ∼ 2 or more.
● Index Mechanism
(1) Specifications and Operating Conditions of the Drive Mechanism
Geared stepper motors are ideal for systems with big inertia, such as index tables.

Table diameter .......................... $D_t = 300$ [mm]
Table thickness .................................. $L_t = 5$ [mm]
Table material .......................... Aluminum (Density $\rho = 2.8 \times 10^3$ [kg/m$^3$])
Load diameter .................................. $D_l = 40$ [mm]
Load thickness .................................. $L_w = 30$ [mm]
Number of loads .................................. 10 (1 every 36˚)
Load material .......................... Aluminum (Density $\rho = 2.8 \times 10^3$ [kg/m$^3$])
Distance from central axis of table to central axis of load .............. $l = 120$ [mm]
Positioning angle .................................. $\theta = 36$˚
Positioning time .................................. $t_n = 0.25$ seconds

The RKII Series PS geared type (Gear ratio 10, resolution/pulse = 0.072˚) can be used.
The PS geared type can be used at the maximum starting/stopping torque in the inertial drive.
Gear ratio .................................. $i = 10$
Resolution/pulse .................................. $\delta_s = 0.072$˚

(2) Determine the Operating Pattern (Refer to formula on page H-5)

1. Calculate the number of operating pulses $A$ [Pulse]

$$A = \frac{\theta}{\delta_s} = \frac{36}{0.072} = 500$$ [Pulse]

2. Determine the acceleration (deceleration) time $t_n$ [s]
An acceleration (deceleration) time of 25% of the positioning time is appropriate.
Here, we shall let $t_n = 0.1$ [s].

3. Calculate the operating pulse speed $f_s$ [Hz].

$$f_s = \frac{A}{t_n - t_i} \approx \frac{500}{0.25 - 0.1} \approx 3334$$ [Hz]

4. Calculate the operating speed $N_u$ [r/min].

$$N_u = \frac{\delta_s}{360} f_s \times 60 \approx \frac{0.072}{360} \times 3334 \times 60 \approx 40$$ [r/min]

The permissible speed range for the PS geared motor with a gear ratio of 10 is 0~300 [r/min].

(3) Calculate the Required Torque $T_L$ [N·m] (Refer to page H-5)

1. Calculate the load torque $T_L$ [N·m]
Friction load is negligible and therefore omitted. Load torque is assumed as 0.

$$T_L = 0$$ [N·m]

2. Calculate the acceleration torque $T_a$ [N·m]

- 1 Calculate the inertia $J_k$ [kg·m$^2$]
(Refer to page H-4 for the formula)

Inertia of Table $J_T = \frac{\pi}{32} \rho \cdot L_T \cdot D_t^2$

$$J_T = \frac{\pi}{32} \times 2.8 \times 10^3 \times (5 \times 10^{-3}) \times (300 \times 10^{-2})^2$$

$$J_T = 1.11 \times 10^{-2}$$ [kg·m$^2$]

Inertia of load $J_W^1$ (Around Center of Load Rotation)

$$J_W^1 = \frac{\pi}{32} \times 2.8 \times 10^3 \times (30 \times 10^{-3}) \times (40 \times 10^{-2})^2$$

$$J_W^1 = 0.211 \times 10^{-2}$$ [kg·m$^2$]

Load Mass $m_W = \frac{\pi}{4} \rho \cdot L_w \cdot D_t^2$

$$m_W = \frac{\pi}{4} \times 2.8 \times 10^3 \times (30 \times 10^{-3}) \times (40 \times 10^{-2})$$

$$m_W = 0.106$$ [kg]

Inertia of load $J_M$ [kg·m$^2$] relative to the center of rotation can be calculated from distance $l$ [mm] between the center of load and center of table rotation, mass of load $m_W$ [kg], and inertia of load around the center of load $J_W$. [kg·m$^2$].

Since the number of loads, $n = 10$ [pcs],

Inertia of Load $J_L = n (J_W^1 + m_W \cdot l)$

$$J_L = 10 \times ((0.211 \times 10^{-2}) + 0.106 \times (120 \times 10^{-2}))$$

$$J_L = 1.55 \times 10^{-2}$$ [kg·m$^2$]

Inertia $J_k = J_T + J_L$

$$J_k = (1.11 + 1.55) \times 10^{-2}$$

$$J_k = 2.66 \times 10^{-2}$$ [kg·m$^2$]
②-2 Calculate the acceleration torque \( T_a \) [N·m]

Calculate the acceleration torque of the output gear shaft.

\[
T_a = \frac{(J_t \cdot i_f^2 + J_L)}{9.55} \cdot \frac{N \cdot m}{0.1} = 4.19 \times 10^5 J_t + 1.11 \text{[N·m]}
\]

The formula for calculating acceleration torque with pulse speed is shown below. Calculation results are the same.

\[
T_a = (J_t \cdot i_f^2 + J_L) \cdot \frac{\pi}{180} \cdot \frac{f_t - f_i}{t_1} = (J_t \times 2.66 \times 10^{-5}) \times \frac{\pi \times 0.072}{180} \times 3.334 \times 0.01 = 4.19 \times 10^5 J_t + 1.11 \text{[N·m]}
\]

③ Calculate the required torque \( T_r \) [N·m]

Calculate safety factor \( S_f = 2 \).

\[
T_r = (T_i + T_a) S_f = [0 + (4.19 \times 10^5 J_t + 1.11)] \times 2 = 8.38 \times 10^5 J_t + 2.22 \text{[N·m]}
\]

(4) Select a Motor

① Tentative motor selection

<table>
<thead>
<tr>
<th>Product Name</th>
<th>Rotor Inertia [kg·m²]</th>
<th>Required Torque [N·m]</th>
</tr>
</thead>
<tbody>
<tr>
<td>RKS566AAD-PS10-3</td>
<td>270 \times 10^{-7}</td>
<td>2.45</td>
</tr>
</tbody>
</table>

② Determine the motor from the speed – torque characteristics

The \( \text{RKS566AAD-PS10-3} \) motor is the equivalent of the \( \text{RKS566AAD-3} \) motor. Since the inertia ratio is 9.85, the operation of the motor is possible.

(6) Check the Acceleration/Deceleration Rate (Refer to page H-5)

Note when calculating that the units for acceleration/deceleration rate \( T_R \) are [ms/kHz].

\[
T_R = \frac{t_i}{f_s - f_i} = \frac{0.1 \text{[s]}}{3334 \text{[kHz]} - 0 \text{[kHz]}} = \frac{3.334 \text{[kHz]} - 0 \text{[kHz]}}{100 \text{[ms]}} = 30 \text{[ms/kHz]}
\]

The \( \text{RKS566AAD-PS10-3} \) motor is the equivalent of the \( \text{RKS566AAD-3} \) and it has an acceleration/deceleration rate of 20 [ms/kHz] or more. Since the acceleration/deceleration rate is 30 [ms/kHz] the operation of the motor is possible.
Selection Calculations

Motors

Winding Mechanism

This example demonstrates how to select winding equipment when a torque motor is used.

(1) Specifications and Operating Conditions of the Drive Mechanism

Winding roller diameter $D$
- Diameter at start of winding $D_1 = 15$ [mm] = 0.015 [m]
- Diameter at end of winding $D_2 = 30$ [mm] = 0.03 [m]

Tensioning roller diameter $D_3 = 20$ [mm] = 0.02 [m]

Winding speed $V = 47$ [m/min] (constant)

Tension $F = 4$ [N] (constant)

Power Single-phase 115 VAC

Operating time Continuous

(2) Select a Winding Motor

In general, a winding motor must satisfy the following conditions:
- Able to provide a constant winding speed
- Able to apply a constant tension to prevent slackening of material

To meet the above conditions, the following points must be given consideration when selecting a motor:
- Since the winding diameter is different between the start and end of winding, the motor speed must be varied according to the winding diameter to keep the winding speed constant.
- If the tension is constant, the required motor torque is different between the start and end of winding. Accordingly, the torque must be varied according to the winding diameter.

Torque motors have ideal characteristics to meet these conditions.

① Calculate the Required Speed

Calculate the speed $N_1$ required at the start of winding.

$$N_1 = \frac{V}{\pi \cdot D_1} = \frac{47}{\pi \times 0.015} \approx 1000 \text{ [r/min]}$$

Calculate the speed $N_2$ required at the end of winding.

$$N_2 = \frac{V}{\pi \cdot D_2} = \frac{47}{\pi \times 0.03} \approx 500 \text{ [r/min]}$$

② Calculate the Required Torque

Calculate the torque $T_1$ required at the start of winding.

$$T_1 = \frac{F \cdot D_1}{2} = \frac{4 \times 0.015}{2} = 0.03 \text{ [N·m]}$$

Calculate the torque $T_2$ required at the end of winding.

$$T_2 = \frac{F \cdot D_2}{2} = \frac{4 \times 0.03}{2} = 0.06 \text{ [N·m]}$$

This winding motor must meet the following conditions:
- Start of Winding: Speed $N_1 = 1000$ [r/min], Torque $T_1 = 0.03$ [N·m]
- End of Winding: Speed $N_2 = 500$ [r/min], Torque $T_2 = 0.06$ [N·m]

③ Select a Motor

Check the Speed – Torque Characteristics

Select a motor that meets the required conditions specified above. If the required conditions are plotted on the Speed – Torque Characteristics for 4TK10A-AW2U, it is clear that the conditions roughly correspond to the characteristics at a torque setting voltage of 60 VAC.

Speed – Torque Characteristics

<table>
<thead>
<tr>
<th>Voltage</th>
<th>Torque [N·m]</th>
<th>Speed [r/min]</th>
</tr>
</thead>
<tbody>
<tr>
<td>115 VAC</td>
<td>0.35</td>
<td>1800</td>
</tr>
<tr>
<td>110 VAC</td>
<td>0.30</td>
<td>1500</td>
</tr>
<tr>
<td>100 VAC</td>
<td>0.25</td>
<td>1200</td>
</tr>
<tr>
<td>80 VAC</td>
<td>0.20</td>
<td>900</td>

<tr>
<td>60 VAC</td>
<td>0.15</td>
<td>600</td>
</tr>
<tr>
<td>40 VAC</td>
<td>0.10</td>
<td>300</td>
</tr>
</tbody>
</table>

Check the Operation Time

4TK10A-AW2U has a five-minute rating when the voltage is 115 VAC and a continuous rating when it is 60 VAC. Under the conditions given here, the voltage is 60 VAC max., meaning that the motor can be operated continuously.

Note
- If a torque motor is operated continuously in a winding application, select conditions where the service rating of the torque motor remains continuous.
(3) Select a Tensioning Motor

If tension is not applied, the material slackens as it is wound and cannot be wound neatly. Torque motors also have reverse-phase brake characteristics and can be used as tensioning motors. How to select a tensioning motor suitable for the winding equipment shown on page H-16 is explained below.

① Calculate the Required Speed \( N_3 \)
\[
N_3 = \frac{V}{\pi \cdot D_3} = \frac{47}{\pi \times 0.02} = 748.4 \text{ [r/min]} \div 750 \text{ [r/min]}
\]

② Calculate the Required Torque \( T_3 \)
\[
T_3 = \frac{F \cdot D_3}{2} = \frac{4 \times 0.02}{2} = 0.04 \text{ [N\cdotm]}
\]

③ Select a Motor
Select a motor that meets the required conditions specified above. If the required conditions are plotted on the speed – brake torque characteristics for the 4TK10A-AW2U reverse-phase brake, it is clear that the conditions roughly correspond to the characteristics at a torque setting voltage of 40 VAC.

Speed – Brake Torque Characteristics with Reverse-Phase Brake

![Graph showing speed vs. brake torque]

Note
- If a torque motor is operated continuously in a brake application, how much the motor temperature rises varies depending on the applicable speed and torque setting voltage. Be sure to keep the temperature of the motor case at 90˚C max.

From the above checks, the 4TK10A-AW2U can be used both as a winding motor and tensioning motor.

Please contact the nearest Oriental Motor sales office or customer support center for information on the speed – brake torque characteristics of each product.
